Convolutional Neural Networks

General Neural net $a_i^j = \sigma(\vec{W}_i^{(j-1)} \cdot \vec{a}^{(j-1)})$

Convolutional Neural net $a_i^j(k) = R\left[\sigma(\vec{W}_i^{(j-1)} \star \vec{a}^{(j-1)}(k))\right]$

Figure: From <http://deeplearning.net/tutorial/lenet.html>

Here a^j is the set of coefficients in layer j , σ is a nonlinearity such as $|\cdot|$ or ReLU, and R is a subsampling operator.

Signal Invariants

How to construct a feature extractor that is invariant to task-irrelevant deformations in the data? Some examples:

Translation	$T_c[f] = f(x - c)$
Modulation	$M_\omega[f] = e^{i\omega t} f(x)$
Scaling	$\mathcal{S}_a[f] = f(x/a)$
Amplitude	$A_a[f] = af(x)$

Signal Invariants

How to construct a feature extractor that is invariant to task-irrelevant deformations in the data? Some examples:

Translation	$T_c[f] = f(x - c)$
Modulation	$M_\omega[f] = e^{i\omega t} f(x)$
Scaling	$\mathcal{S}_a[f] = f(x/a)$
Amplitude	$A_a[f] = af(x)$

[?] and [?] demonstrated that only trivial linear features are absolutely invariant to even just translation, so they use *relative invariance* of feature extractor ρ :

$$\rho[T_c f] = \eta(c)\rho[f]$$

[?] and [?] demonstrated that only trivial linear features are absolutely invariant to even just translation, so they use *relative invariance* of feature extractor ρ :

$$\rho[T_c f] = \eta(c)\rho[f]$$

They establish that the only linear feature extractors $\rho[f] = \langle f, \rho \rangle$ that are relatively invariant w.r.t. both amplitude and translation deformations are Fourier-Laplace type, i.e. for some $z \in \mathbb{C}^d$

$$\int_{\mathbb{R}^d} f(x) c_1 e^{z \cdot x} dx$$

Edge detection & local features

Fourier coefficients have a couple of problems:

- Detects global features, rather than local
- Slow decay rate for signals with sharp edges, e.g. images

Loosening the translation invariance further, we have translation *covariance*: $\rho[T_c f] = T_c \rho[f]$, which implies a convolutional filter $\rho[T_c f] = g_\rho \star f$. Many examples adapted to address both of the above, e.g. Wavelets, Curvelets, Shearlets.

Shearlets

A particularly useful class of edge detectors for ≥ 2 D data, the filters are indexed by shearing, scale, location and cone:

$$\begin{aligned}\mathcal{S}_1[f] &= (f \star \phi, f \star \psi_{j,k}) \\ \psi_{j,k}(x) &= 2^{(2+\alpha)j/4} \psi(A_j^{-1} S_k^{-1} x) \\ A_j &= \begin{pmatrix} 2^j & 0 \\ 0 & 2^{j\alpha/2} \end{pmatrix} S_k = \begin{pmatrix} 1 & ck \\ 0 & 1 \end{pmatrix}\end{aligned}$$

Previous Theory

Translation

The first results on Scattering transforms were from [?] and his group. A more recent generalization for systems like shearlets, relates depth m to translation:

Theorem (Translation invariance, [?])

As long as the frames have upper frame bounds b_m satisfying $\max\{b_m, \gamma_m b_m / r_m^d\} \leq 1$, the features at depth m satisfy:

$$S^m[T_c f] = T_{\frac{c}{r_1 \cdots r_{m-1}}} S^m[f]$$

Further if the output atoms satisfy $\widehat{\phi}_m|\omega| \leq K$, this implies a bound on the difference in norm:

$$\|S^m[f] - S^m[T_c f]\| \leq \frac{2\pi|c|K}{r_1 \cdots r_m} \|f\|_2$$

The Shattering Transform

David Weber and Naoki Saito

Signal Invariants and Edge detection

Scattering Transform

Shattering Transform

Sonar Classification

In addition to this quasi-translation invariance, this generalized scattering transform is stable under space and frequency modulations:

$$F_{\tau,\omega}[f](x) = e^{i\omega(x)} f(x - \tau(x))$$

Theorem (Stability, [?])

If f is a band limited function, ω and τ are continuous, τ is once differentiable and $\|\nabla\tau\|_{\infty} \leq \frac{1}{2d}$, there is a C independent of S so that

$$\left\| S[f] - S[F_{\tau,\omega}[f]] \right\|_2 \leq C \|f\|_2 (R \|\tau\|_{\infty} + \|\omega\|_{\infty})$$

where the norm on S is just $\|\cdot\|_2$ on each output element

The Shattering Transform

David Weber and Naoki Saito

Signal Invariants and Edge detection

Scattering Transform

Shattering Transform

Sonar Classification

Shattering transform

using a shearlet scattering transform, in addition to the previous result, we have that the coefficients decay at the same rate as the linear coefficients:

Theorem (Sparsity)

Assume that the input image f is a cartoon-like function, i.e. has the form $f = f_0 + f_1\chi_B$, where f_i is smooth, and ∂B is a C^2 function, and that σ is smooth at all but one point. If we denote the reordering of $S[f]$ by size as c_i , we have that

$$|c_i| \approx O\left(\frac{\log n}{n^{3/2}}\right)$$

We have implemented the Shattering Transform in Julia in the package `COLLATINGTRANSFORM.JL` (to be released in the next 6 months)

Setup Description

We use Mallat's framework with Morlet Wavelets, and compare with the absolute value of the Fourier transform (AVFT). We use two scattering transforms:

Type	Q ₁	Q ₂	Q ₃
Finer	8	8	1
Coarser	8	4	4

- Each signal is normalized so the maximum amplitude is 1
- White Gaussian noise is added to get average SNR is about 5dB.
- Multiclass logistic regression with Lasso (via GLMNET) is used as a feature extractor and a classifier.
- Perform 10-fold cross validation, i.e., repeat the classification 10 times by randomly splitting the whole dataset into training and test sets with 50/50.
